The Impact of Region of Origin on Income: Analyzing Earnings Disparities Among Canadian Immigrants

By Karl Estampador, Charlotte Lai and Merry Liu *

This paper investigates whether immigrants from certain regions earn more in Canada and identifies key determinants of their total income. More specifically, if region of origin is a key factor in income inequality. Using data from the 2021 Canadian Census PUMF, a random sample of the 2021 census, we use OLS regression models on immigrants, accounting for factors such as: education, field of study, occupation, language ability, and age at immigration. Results show significant income disparities across regions of origin, with higher earnings among immigrants from Western Europe and North America. Educational attainment and age at arrival are strong predictors of income, with interaction effects revealing regional differences in returns to education. The findings highlight persistent structural inequalities in the Canadian labour market for immigrants.

I. Introduction

Today, with the progress of globalization, the impact of immigrants on the national economy and social system is increasingly significant, and more scholars focus on the study of the ecology of immigrants in the labor market. Immigrants are a large and complex community with diverse linguistic and cultural backgrounds. Understanding intra-migrant income disparities has important policy implications for providing targeted support and more efficient resource allocation schemes.

Previous research on income differences among immigrants provides a good foundation for this project. The study done by Scott et al. (2021) highlights immigration status to be a determinant for income and can be extended to reflect societal perceptions regarding immigrants in the labour market. The research done by Boudarbat and Lemieux (2014) has proved that wages of immigrants vary significantly across factors, one of which being country of origin. These studies contribute to the construction of a deeper understanding of immigrant groups' engagement and interaction in the labor market. However, few studies have isolated the impact of differences in immigrants' birthplace on income. Therefore, this paper aims to investigate the income disparity among immigrants from different regions, addressing a key gap in the existing research. The research question is whether immigrants from certain regions have a systematic advantage

*

in terms of income compared to immigrants from other regions. The target is to investigate the persistent effect of place of birth on income disparity, isolated from common explanatory factors such as education level, language ability, age, gender, and occupation.

Understanding whether and why certain immigrant groups achieve higher economic success than others can provide valuable insights for policymakers promoting equality and diversity in Canada's economy. The analysis uses robust statistical methods to identify and quantify income disparity among immigrant groups and adjusts for relevant control variables. The results of this study will contribute to the ongoing discussion on how immigrants integrate into local markets and refine the investigation of the factors that influence immigrant income inequality.

II. Data Description

The Canadian Census is done every five years, and provides a statistical representation of Canada against many variables regarding demographic, social, and economic characteristics. The data set (Statistics Canada, 2023) used is a subset of data from the 2021. Statistics Canada, the government sector that collects this data, mailed every Canadian household the census and conducts published research using the data from the census.

The Canadian Census is mailed to all Canadian households. Typically, one member of the household will fill out the questionnaire on behalf of the household, as there are overlapping questions. Generally, there should not be any shared characteristics in the participants besides the location of their current residence. It should be noted that this subset of data does not include people living in institutions; Canadian citizens living temporarily in other countries; full-time members of the Canadian Forces stationed outside Canada; persons living in institutional collective dwellings such as hospitals, nursing homes and penitentiaries; and persons living in non-institutional collective dwellings such as work camps, hotels and motels, and student residences.

Our primary independent variable is place of birth (POB), as we are investigating how POB affects the total income of immigrants in Canada. To control for POB, we have many control variables, which are shown in the list of variables in the page below:

Table 1—: Description of Independent Variables Used in the Regression Model

Variable	**Description**
POB (primary)	Place of birth (captures regional differences in income among immigrants)
HDGREE (control)	Highest degree earned (controls for the effect of educational attainment on income)
CIP2021 (control)	Field of study (accounts for variation in income by academic discipline)
LOCSTUD (control)	Location of highest education completed (distinguishes returns to foreign versus Canadian education)
noc21 (control)	Occupation category (controls for income variation across different job types)
KOL (control)	Knowledge of official languages (shows language proficiency's role in an immigrant's success in the labour market)
AGEIMM (control)	Age at immigration to Canada (affects ease of integration into Canada and long-term earnings)
Gender (control)	Self-identified gender (captures gender-based disparities in earnings)
MarStH (control)	Marital status (associated with household structure and economic support)
HHSIZE (control)	Household size (controls for family size effects on reported income)
POB:HDGREE (control)	Interaction between place of birth and educational attainment (tests whether returns to education vary by an immigrant's origin)
AGEIMM:HDGREE (control)	Interaction between age at immigration and educational attainment (examines how timing of arrival into Canada affects educational returns)
POB:LOCSTUD (control)	Interaction between place of birth and location of highest education completed (captures value of foreign education across regions based on an immigrant's origin)

III. Summary Statistics

Since most of our control variables are categorical variables, we included the frequency table for an immigrant's place of birth, and included the rest of the frequency tables for the control variables in the appendix between tables A1 to A9.

Table 2—: Frequency Table for an Immigrant's Place of Birth

Category	Count	Percent
USA	38	2.64
Central + South America	159	11.03
Northern + Western Europe	225	15.62
Southern + Eastern Europe	148	10.27
Africa	100	6.93
Middle East + West Central Asia	107	7.43
China	116	8.05
East Asia (excluding China)	82	5.69
Philippines	119	8.26
Southeast Asia (excluding Philippines)	44	3.05
India	146	10.13
South Asia (excluding India)	62	4.3
Oceania + others	8	0.56
N/A	87	6.04

In table 3, we see that total income is skewed to the right, as very few people have a high level of income and most people have a low to moderate income. We will address this issue in the model specification.

Table 3—: Summary Statistics for Total Income

	Mean	SD	Min	Max	N
TotInc	48 961.77	43 822.44	1.00	452 570.00	1441

IV. Model Specification

The key assumptions behind our OLS regression model are as follows. First we assume that the relationship between the dependent and independent variables is linear. Next, we assume that observations are independent of each other. Thirdly, we assume that the error terms are homoskedastic. Fourth, we assume that the

model's residuals are normally distributed. Finally, we assume rare large outliers, namely that the variables have finite fourth moments.

In order to create a robust regression model, we tested for multicollinearity through the VIF test. However, we were unable to include the interaction variables in our VIF test, since there was a high number of dummy variables leading to high multicollinearity. In our VIF test, we saw that LOCSTUD had high multicollinearity. This could because of its high overlap with place of birth, as people born in a certain country tend to study there. However, we will keep LOCSTUD in our regression, as where an immigrant studies can have a strong impact on increasing their total income. The VIF table is shown below:

Table 4—: Generalized Variance Inflation Factors (GVIF) for Key Predictors

Variable	**GVIF**	**Df**	**VIF score**	**Other Predictors**
POB	6.091e+01	31	1.068527	HDGREE, CIP2021, LOCSTUD, noc21, KOL, AGEIMM, Gender, MarStH, HHSIZE

To investigate the impact of region of origin on income, we use the variables listed above to create our first model, where X_2 up to X_{13} are the control variables listed above in our table of variables. Hence our original model had a regression equation:

$$TotInc = \beta_0 + POB\beta_1 + X_2\beta_2 + \cdots + X_{13}\beta_{13} + \epsilon$$

However, we used a log-linear model with the equation:

$$\log(TotInc) = \beta_0 + POB\beta_1 + X_2\beta_2 + \cdots + X_{13}\beta_{13} + \epsilon$$

We decided to use a log-linear model since total income was the only non-factored variable that had a high maximum, low minimum, and large standard deviation. This caused the distribution to be skewed to the right, as most people earn low to moderate levels of income. Hence, log-transforming total income enables our interpretations to be more meaningful, where we can investigate the percentage change based on a change in a regressor.

We also used different variations of the original model to increase robustness. While one variation included both the log-transformation and grouping the variable "NOC21" into more broader categories, one variation included only the log-transformation, while another variation included only the grouping of NOC21 into broader categories, which is seen in table A8. After running the regression, we see that variations that use the log-linear model have more significance, while those that do not use the log-linear model do not show significant results to the same degree.

Furthermore, to address heteroskedasticity, we used a heteroskedasticity-robust estimator, and we will use this estimator's results in the table of results and in the discussion.

V. Table of Results

Tables A10 to A13 show all the results significant at the 5% level, while table 5 shows a representative sample of the significant results which we will go into more detail in the discussion. The full table of results is shown from tables A14 to A33. Note that for the tables in the appendix, estimates marked with a + show significance at 10%, as well as *. These symbols are used interchangeably by the model. Table 5, which is the summarized table of significant results is shown in the page below, to ensure readability.

VI. Discussion

This discussion section will namely talk about the significant results from the OLS regression performed by the log-linear model, due to the sheer number of estimated coefficients given by the model, which gave us approximately 500. Hence, these results mentioned in this section offer meaningful insights regarding a variety of factors that can lead to an immigrant's place of birth determining their

levels of total income.

An immigrant's place of birth can have some impact on their income, as immigrants from Europe, the Middle East, and most parts of Asia tend to have a higher income compared to Canadians, while immigrants from Southeast Asia have lower total income levels. This shows that income disparity is present between different places of birth, as immigrants from European countries tend to have more of their credentials recognized in Canada compared to immigrants from Southeast Asia, who may come from not as respected institutions. However, what is fascinating and surprising is that while the results show that immigrants studying in Europe tend to make 2% less than those who studied in Canada, immigrants from Southeast Asia and East Asia who studied in Europe, tend to have a higher income than immigrants who studied in Canada by between 2.5% to 4%. This result contradicts the idea where foreign education is a disadvantage, especially for Southeast Asian and East Asian immigrants who may have language barriers which may further decrease their income. It also contradicts the result we had where immigrants studying in Europe tend to make 2% than those who studied in Canada. This result may be possible due to the caliber of Southeast Asian and East Asian students who are able to study in Europe, as they may be more skilled, ambitious, or wealthy, and may tend to pursue more in-demand fields.

Conversely, the results are mixed regarding the interaction effects between place of birth and highest education achieved among immigrants, causing mostly lower income levels to Canadians with the same education level, with some positive outliers. For instance, immigrants from Southern Europe and Southeast Asia with an apprenticeship certificate tend to have a higher income than Canadians with an apprenticeship certificate by between 4% to 7%, while immigrants from South and East Asia with the same education level have lower income than Canadian apprentices by at least 3%. Additionally, immigrants with a Master's degree or higher tend to have lower total income than Canadians with the same credentials, regardless of their place of birth. The only exception to this is that immigrants from Northern Africa with a degree in medicine or a related field tend to outearn their Canadian peers by 5.5%. Furthermore, immigrants from Southeast Asia with a Bachelor's degree tend to earn than Canadians with a Bachelor's by 3.9%. Hence, the results suggest that certain combinations of place of birth and practical credentials yield higher returns compared to Canadians with the same credentials. These combinations mainly benefit immigrants from Southeast Asia, who experience the most amount of increased income relative to Canadians at both a Bachelor's degree level and at an apprenticeship level.

There are many negative interactions between age immigrated and highest level of education achieved. For instance, immigrants who immigrated to Canada between the ages of 20 and 40 with an education in non-apprenticeship trades experienced between 2.2% to 3.6% less income than those who immigrated at a younger age with the same educational background. This may be due to issues regarding transferring credentials to Canada, the difficulty of starting a new life

abroad in Canada, or due to a loss of early-career earnings from their home country.

Despite the valuable insights provided by the regression analysis, there are several limitations that must be acknowledged. First, the model includes approximately 500 estimated coefficients, increasing the risk of Type I error. Additionally, while the model controls for many observed characteristics such as education and age at immigration, our model may still omit many key variables that can influence total income, especially as our R^2 value is only 0.10. Furthermore, the model does not account for broader social or cultural factors such as systemic racism, which can shape total income and help explain some of the income disparities between different ethnicity groups.

Our results match those of Fortin et al. (2016), which also found that region of origin plays a large role in the income gap between immigrants in Canada. Their study examines the difference between foreign degrees and degrees obtained in Canada. The study uses data from the 2006 Canadian Census, and regressed weekly wage onto a wide set of variables, such as: country of origin, gender, education, age at immigration, and other known determinants of income. One variable they also included was location of degree obtained. This question was first introduced in the 2006 census, and is critical to examine if the source of human capital contributes to wage disparity. The study highlights that not only is there a wage gap between foreign and domestic degrees, there is also large wage differences across immigrants depending on their country of origin.

VII. Conclusion

This paper determined that region of origin is a significant and persistent factor in explaining income disparities among immigrants in Canada, using a randomized sample of data from the 2021 Canadian Census and OLS regression. We found that immigrants from Western Europe and North America tend to earn more than those from regions such as Southeast Asia and Eastern Africa, even after controlling for factors such as: education, language proficiency, occupation, and age at immigration.

We also found strong associations between foreign education, age of arrival, and total income, with interaction terms suggesting that the income returns to education vary substantially by region and time if immigration. These findings are consistent with the empirical literature which reports immigrants from regions who are more culturally and economically similar to Canada, for example Western Europe and the United States, report higher income returns compared to their counterparts from less aligned regions. This hints to systemic barriers to integrating into the Canadian labour force.

Further research can be done to explore the income difference, and examine long-term integration patterns and policy impacts.
